## ABSTRACT

**AIM:** To evaluate the safety and efficacy of flow diverter (FD) stents in the treatment of intracranial aneurysms less than 5 mm.

**MATERIAL and METHODS:** We treated 66 aneurysms in 43 patients with aneurysms less than 5 mm. Of the patients, 29 were females and 14 males (mean age: 50.2 years). Headache was the most frequent symptom. In 8 patients the aneurysms were recanalized and these had been treated with coils or stent-assisted coiling. All aneurysms were in the anterior circulation. In the treatment, one of the SILK, Pipeline, Derivo or FRED FD stents was used for each patient. Neurointerventional stent medication (double antiplatelet) was used. All patients were investigated for new ischemic lesions with diffusion-weighted imaging one day later. The first follow-up angiogram was planned 3-6 months later.

**RESULTS:** The treatment was technically successful in all patients. Minor complications occurred in 3 patients (7%). In one patient, thrombus inside the SILK was seen and was relieved with tirofiban. The second patient bled from the right common femoral artery entrance, which was operated on. In the third patient, the complication was technical. All patients were discharged without any neurological deficit. The mean follow-up period was 26 (6-52) months. Of the aneurysms, 64 (97.0%) were completely closed.

**CONCLUSION:** The FD treatment of cerebral, anterior circulation small aneurysms less than 5 mm is effective and safe.

## INTRODUCTION

Big, wide-necked, and fusiform cerebral aneurysm treatment with flow diverter (FD) stents is a milestone in interventional neuroradiology. The high rate of successful treatment, low rate of aneurysm recanalization, easy insertion, and short duration of procedure mean that FDs are preferred as the first choice of treatment. The efficacy and safety of FD treatment of these aneurysms have resulted in its widespread use for all kinds of aneurysms, including ruptured or unruptured small or blister-like ones, which are difficult to treat (4,6,8,9,13,16,19,23,27,30).

We evaluated the safety and efficacy of FD stents by analyzing the procedural complications, angiographic results, and clinical outcomes in the treatment of intracranial aneurysms of less than 5 mm with certain indications.

## MATERIAL and METHODS

In this retrospective study, we treated 66 aneurysms less than 5 mm in size in 43 patients. The Institutional Ethics Committee approved the study (Date: 19.02.2020; No: 191). Written and signed informed consent was obtained from each patient. Of the patients in the study, 29 were females and 14 males (mean age: 50.2 years). We treated small aneurysms in patients with headache, ophthalmoplegia, or subarachnoid hemorrhage (SAH) (in late phase), and the ruptured or unruptured aneurysms larger than 5 mm were surgically or endovascularly managed, but their recanalization size was less than 5 mm. Only 8 aneurysms were incidentally detected, but they were associated with the additional larger aneurysms treated endovascularly or surgically. An internal carotid artery (ICA) cavernous small aneurysm associated with other parophthalmic aneurysms was treated. Headache was the most frequent symptom. In 8 patients, the aneurysms were recanalized, and these had been treated with coils only (4 aneurysms) or stent-assisted coiling (4 aneurysms). In one patient with SAH, the ophthalmic aneurysm was treated with Derivo one month after hemorrhage. All aneurysms were in the anterior circulation. Of 66 aneurysms, 6 were beyond the ICA bifurcation. In the treatment, only one of the brands [SILK, Balt, Montmorency, France; Pipeline Embolization Device (PED), Medtronic Covidien AG, Paris, France; Derivo, Acandis, Pforzheim, Germany; Surpass, Stryker Neuroendovascular, Kalamazoo, MI, USA; or FRED, Microvention Terumo, Tustin, CA, USA] was used for each patient. Table I reveals the demographic and clinical data of the study population.

### Endovascular Technique

After general anesthesia, access to the ICA was gained using neurovascular long introducers and distal access-guiding catheters. Before insertion of the FD, if coiling was planned, embolization was performed via a microcatheter with or without use of an aneurysm neck-remodeling balloon. A microcatheter, which is suitable to deploy the chosen FD, was inserted in the parent artery using a 0.014 or 0.016 micro guidewire, the distal end of the microcatheter passing the aneurysm neck by about 2 or 3 cm. Then the FD was deployed to cover the neck of the aneurysm. Correct expansion of the

FD was detected under fluoroscopy, and a remodeling balloon was applied to provide proper apposition of the stent to the vessel wall in case of improper apposition. Table II shows the procedural data.

**FD:** Flow diverter.

### Medication

Intracranial stent medication was accomplished. Double antiplatelet medicines (acetylsalicylic acid and clopidogrel) were administered 7–10 days before the treatment. In case of resistance, aspirin dosage was increased, and clopidogrel was replaced by ticlopidine, ticagrelor, or prasugrel. The aspirin was ordered to be continued indefinitely, and clopidogrel or ticlopidine was discontinued after 6 months in patients over 50 years old. If a problem arose concerning aspirin sensitivity or gastrointestinal intolerance, aspirin was discontinued, and lifetime usage of other antiplatelet medicine was ordered. If the patient was under 50 years old, the duration of the total usage of antiplatelet medicine was planned as 3–4 years.

After entering the femoral artery, 5000 IU heparin was given intravenously, maintaining 2 or 3 times the baseline value, and the serum-activated coagulation time (ACT) was controlled. During the procedure, 1000 IU or more of heparin was administered per hour to maintain the ACT level as stable. After the procedure, 750–1000 IU/h heparin was infused for 24 hours. Low-molecular heparin (1 or 2 x 0.4–0.6 ml) was given subcutaneously for 1–5 days after IV heparin.

### Follow-up

After the procedure, flat panel computed tomography (CT) was done to find out any procedural hemorrhagic complications. All patients were investigated for any ischemic focus with diffusion-weighted imaging one day later. The first and second follow-up angiograms were planned for 3–6 and 9–18 months later respectively.

## RESULTS

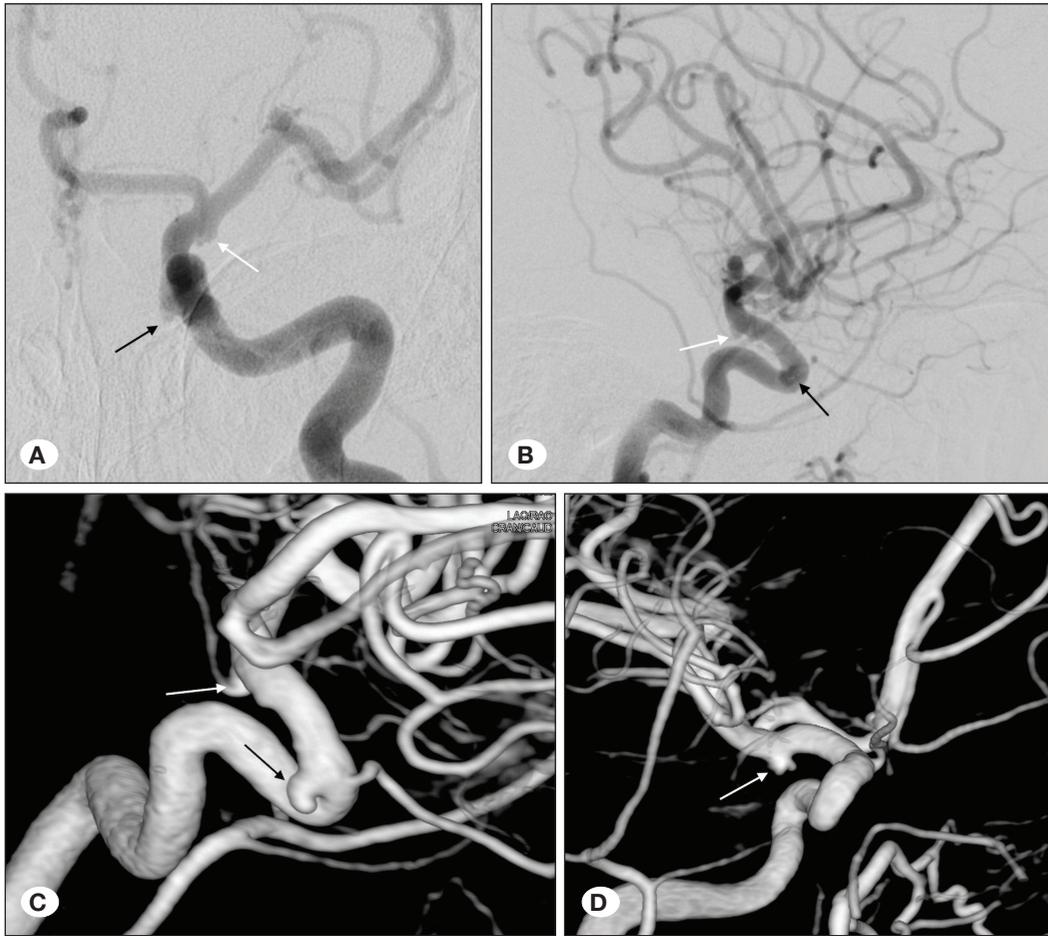

The treatment was technically successful in all patients. In 3 patients, two FDs were used. Two patients had aneurysms bilaterally, and in another patient, the FD (Surpass) caused angulation of the middle cerebral artery. This angulation was treated with a second Surpass placed distally. The most used FD was the SILK (52.2%), and the second was the Derivo FD (19.6%). The number of FDs per case was 1.1, and the number of FDs per aneurysm was 0.7 (Table II).

Minor complications occurred in 3 patients (7%). In one patient, thrombus inside SILK was seen, which was relieved with tirofiban. However, some asymptomatic acute focal small ischemic lesions were seen on follow-up magnetic resonance imaging (MRI). The second patient bled from the right common femoral artery entrance, which was operated on. In the third patient, complication was technical. The Derivo FD was stuck in the microcatheter during insertion, so a new Derivo was inserted. Hemorrhagic complication was not seen on CT performed immediately after the procedure. All patients were sent home without any neurological deficit.

The mean follow-up period was 26 (6–52) months. Of the 66 aneurysms, 64 (97.0%) were completely closed (Table III). In the other 2 patients, 2 aneurysms were still filling at their follow-up angiographies. One of the patients had 2 ICA ophthalmic segment small aneurysms located on the anterior and posterior wall and was treated with a SILK FD. A 48-month angiogram revealed that the anterior wall aneurysm was still filling, while the other one was completely closed. In the other patient, a recanalized aneurysm previously treated with stent-assisted [Enterprise: Codman Neurovascular, Inc., Raynham, MA, USA (formerly Cordis, Johnson and Johnson Medical, Miami, FL, USA)] coiling was treated with a SILK FD device, and the aneurysm was still filling at the 18-month angiography. Figures 1A–D; 2A, B; 3A–D show a representative case.

## DISCUSSION

Because the usage of FDs in the treatment of intracranial complex, wide-necked big and giant, and fusiform aneurysms has been highly effective and safe, many studies showing

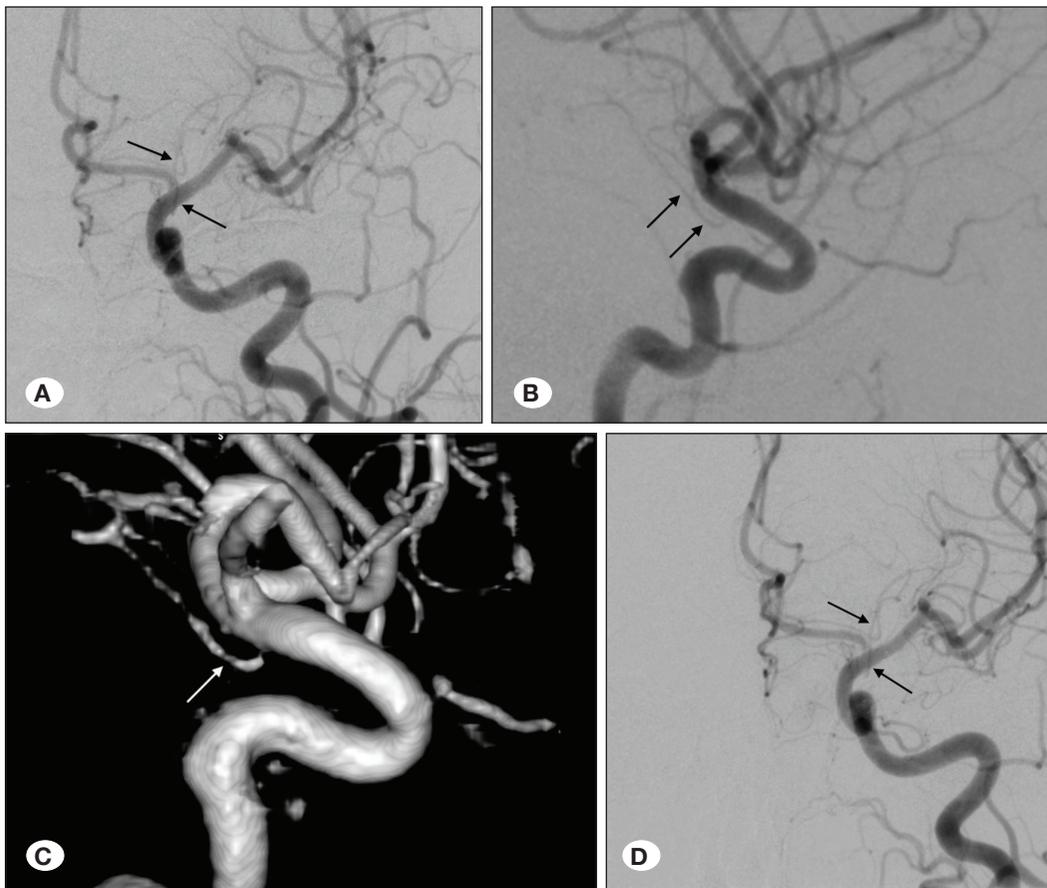

**Figure 1:** A 49-year-old patient suffering from headache was evaluated with digital subtraction angiography and 2 small aneurysms (A-D) of the left internal carotid artery ophthalmic segment (black arrows, A-C) and anterior choroidal artery (white arrows, A-D) were seen.

**Figure 2:** A Derivo flow diverter stent was implanted (A and B).

the feasibility and effectivity of the FDs in the treatment of nearly all kinds of aneurysms, ruptured or unruptured, located proximal or distal to ICA bifurcation, or either in the anterior or posterior circulation, have appeared in recent years (6,7,10,13,17,23,24,26,27,30,31). Those aneurysms

treated with FDs also include blister aneurysms. Surgical procedures or conventional endovascular treatment of blister aneurysms is challenging, but their treatment with FDs has provided satisfactory advancement by reducing the morbidity and mortality (12,23,29). The FD technique relies on the

**Figure 3:** The 3- (A-C) and 9-month (D) angiography showed complete closure of 2 aneurysms. Although the aneurysm had disappeared, the anterior choroidal artery was still patent (black and white arrows, A-D).

endoluminal reconstruction concept of the parent artery and the exclusion of the aneurysm from the blood flow. The flow stasis inside the aneurysm causes an inflammatory reaction, followed by thrombosis and healing of the aneurysm, while the stent helps with neointimal proliferation and remodeling of the parent vessel (2).

Treatment indications of small unruptured aneurysms are not clearly defined. Although their natural course is unclear, the annual rupture risk is extremely low. However, once rupture occurs, morbimortality is extremely high. No conflict exists regarding decision-making for patients with large or small ruptured aneurysms needing to be treated, given the high risk of re-rupture within the first days and weeks (11,22,25). That said, timing or indications of treatment of the unruptured small aneurysms is not defined. Burkhardt et al. (11) reviewed the current evidence for the management of unruptured small cerebral aneurysms, recommending treatment of small unruptured aneurysms in case of being symptomatic, lower treatment risk than rupture risk including an SAH from another ruptured aneurysm, family history (first degree), and any related genetic disease. Aneurysm features, such as anatomic location, a borderline size (5–7 mm), and aneurysm shape with blebs or multiple lobules, were conditions for which management was favored. The researchers considered the patients' age and decided in favor of aneurysm treatment

if the patients were under 50 and in favor of clinical follow-up if over 70. In our study, all treated aneurysms caused symptoms or were associated with other aneurysms that were endovascularly or surgically treated or were recanalized after clipping or embolization. The symptoms of the patients in our study were headache, ophthalmoplegia, and SAH (treated in late phase). Only 8 aneurysms were incidentally detected, but they were associated with the additional larger aneurysms treated endovascularly or surgically. Of 3 patients over 70 years old, only 2 had symptoms: One had speaking disturbance, and the other had headache and 2 aneurysms of the ICA ophthalmic and cavernous segment. The third patient was treated for unruptured middle cerebral artery bifurcation aneurysm with Y-stenting technique and had a 5 mm small unruptured aneurysm.

The optimal management of these small aneurysms remains uncertain despite the appearance of the new less invasive endovascular and microsurgical treatment techniques. Coiling with or without a device-assisted technique in the management of these small aneurysms was the preferred technique before FD devices. The rates of leaving remnant and recanalization are high in these aneurysms' treatment. Perioperative complications are also not inconsiderable (3,20,25,32). Oishi et al. reported that 481 small (<10 mm) asymptomatic and unruptured aneurysms were treated with or

without balloon-assisted coiling. In their study, the immediate complete occlusion rate was 64.2%. Procedure-related complications were seen in 38 patients (7.6%), but permanent morbidity (0.8%) and mortality (0.2%) were extremely low. In contrast, the recanalization rate was high in 427 aneurysms for which a conventional or MR angiographic follow-up was performed at >6 months (n=72, 16.9%). Retreatment was performed in 9.9% of aneurysms. The authors concluded that even though the role of endovascular treatment as a prophylactic therapy remained controversial, endovascular treatment of small asymptomatic unruptured aneurysms was highly effective and safe with low morbimortality rates (25). In Loumiotis et al's study including 65 patients with 69 small aneurysms (<10 mm), treated with only coiling, balloon-, or stent-assisted coiling, FD (only in one), or only stent (only in one), the immediate occlusion rate was 25.6% and the final occlusion rate was 48.8%. A periprocedural complication was seen in 6 patients (9.2%), permanent morbidity in one, and mortality in another patient. A late complication that resulted in a permanent neurologic deficit was seen in one patient (20). In their meta-analysis, Yamaki et al. analyzed 22 studies with 1105 small ( $\leq 3$  mm) aneurysms, including 844 ruptured and 261 unruptured endovascularly treated ones. Postprocedural and long-term complete occlusion were obtained in 85% and 91% of these aneurysms, respectively. The rate of recanalization was 6%, and retreatment was conducted in 7% of cases. Seventy-nine percent of patients' neurologic outcome was good at long-term follow-up. Rupture during the procedure occurred in 7% of the embolizations, while embolic complications were seen in 4%. The researchers concluded that extremely small cerebral aneurysm embolization with coil could be safe and effective. Procedure-related complications were considerable in the unruptured aneurysms (32).

In recent reports, treatment of small aneurysms with FDs has been shown to be feasible and effective (8,9,13,14,33). However, experience remains limited. Lin et al. (19) treated 53 ICA aneurysms smaller than 10 mm with PED in 41 patients. PED was successfully placed in 42 of 44 treatments (95.5%). Though major complications were seen in one patient (2.3%), who died due to early SAH, minor complications occurred in 3 patients (6.9%). These were transient neurological deficits, late asymptomatic intracerebral hemorrhage, and delayed groin infection. Complete or near-complete aneurysm occlusion at 6-month follow-up angiography was seen in 80%. The number of PEDs implanted per treatment was 1.1. One PED was implanted in 37 (88.1%) treatments, and 2 PEDs were implanted in 5 (11.9%) treatments. In their meta-analysis, Yao et al. analyzed 10 observational studies. The rate of complete aneurysm occlusion was 84.23%. The mortality and morbidity rates, including intracerebral hemorrhage, ischemia, and SAH, were 0.87% and 5.22%, respectively. The permanent morbidity (procedure-related) was 2.41% (33). In their study including 104 patients, Pumar et al. assessed retrospectively the safety and efficacy of the SILK FD in the treatment of 109 small unruptured cerebral aneurysms less than 10 mm. A total of 44 patients were symptomatic (42.3%), and 102 aneurysms (93.6%) were in the anterior circulation. At 6 months, the

neurologic morbidity and mortality rates were 2.9% and 0.9%, respectively. The 12-month follow-up imaging revealed complete occlusion, residual neck, and residual aneurysm in 88.5%, 7.7%, and 3.3% of 78 cases, respectively (27).

In our study group, 64 of the 66 aneurysms (97.0%) were completely closed during the mean follow-up period of 26 (6–52) months. Minor complications, one technical and two clinical, were seen in 3 patients (7%) without any permanent neurologic deficits. No mortality was seen. Amongst our patients, only one patient's aneurysm was ruptured, and this aneurysm was treated one month later, not in the acute phase. Thus, we can assume that all aneurysms in our study were unruptured during treatment.

Another indication of the aneurysm treatment with FD is the remnant or recanalization of the aneurysms previously clipped or endovascularly treated with other techniques beyond FD (1,5,15,18,21,28). Schwartz et al. treated 6 patients with recurrent aneurysms that were previously clipped and encountered no periprocedural morbidity or mortality. They concluded that endovascular treatment with FD in those patients was a feasible treatment with low risk and might prevent the risks of resurgery (28). Daou et al., Kühn et al. and Bender et al. treated recurrent or remnant aneurysms after surgical clipping or endovascular treatment with Pipeline FD and reported that the management of these aneurysms with FD is feasible, safe, and effective (5,15,18). In our study, there were 8 recanalized aneurysms less than 5 mm in 8 patients. Of these aneurysms, 4 had been treated with stent-assisted coiling. A patient with ICA ophthalmic segment aneurysm treated with an Enterprise stent and coil displayed recanalization. This aneurysm, treated with SILK FD, was still filling at the 18-month follow-up angiography. However, other recanalized aneurysms treated with coiling or stent-assisted coiling were completely closed during the follow-up.

### Study Limitations

Our study has some limitations: It is retrospective, and there is no control group. Even though the patients' symptoms and treatment indications were inhomogeneous, all aneurysms were considered together. Additionally, FD stents used in the treatment were of different brands. That said, it should not be forgotten that all FDs used in cerebral aneurysm treatment have been reported to have similar efficacy and safety in the literature (2,9,13,27).

### CONCLUSION

FD stents are effective and safe in the treatment of intracranial, anterior circulation small aneurysms less than 5 mm in size. The treatments of these aneurysms have high complete occlusion rates, and the complication rates are low. The FD indications for small intracranial aneurysm treatment can be extended. Even though there are many benefits of treating small symptomatic or asymptomatic incidental or recanalized intracranial aneurysms, in some incidences, there may be risks in the treatment of such aneurysms. This can be clarified through some long-term randomized clinical trials.
