#### Abstract

The acid dissociation $\left(\mathrm{K}_{\mathrm{a}}\right)$ constants of some 4 -and/or 6 -substituted-2-aminobenzothiazole compounds have been investigated theoretically. The gas and aqueous phase geometries, thermal and solvation free energies have been calculated with full geometry optimization by using HF ( $6-31 \mathrm{G}(\mathrm{d})$ ) and B3LYP ( $6-31 \mathrm{G}(\mathrm{d})$ ) methods for 2-aminobenzothiazole, 2-aminothiazole derivatives and their fixed models. From the calculated acidity constants of investigated compounds, it has been detected that the protonation occurs at the the nitrogen atom of the amino group for 2 -aminobenzothiazoles and at ring nitrogen atom for 2 -aminothiazoles. Acceptable correlations have been observed between theoretically (HF and B3LYP) and experimental $p \mathrm{~K}_{\mathrm{a}}$ values of the molecules with regression coefficients $\left(\mathrm{R}^{2}=0.98,0.86\right)$ and $\left(\mathrm{R}^{2}=0.98,0.85\right)$ for the protonation of benzothiazole and thiazole molecules, respectively. Theoretical calculations also show that basicity of the studied compounds increase in the presence of electron donor substituents.

Keywords: 2-Aminobenzothiazole, 2-aminothiazole, $p \mathrm{~K}_{\mathrm{a}}$ calculation, theoretical calculations, PCM

Determination of the acid-base properties of organic compounds benefits the chemical industry. Determination of acidity constants of organic compounds in various solvents is very important as they explain the reaction mechanisms in organic chemistry, clarify the role of substrates attaching to enzymes in biochemistry, and help to design new drugs in the pharmaceutical industry ${ }^{1-14}$.
Benzothiazole derivatives are the members of "azoles" family and they are known for their high biological activities ${ }^{15-23}$. On the other hand, complex formation studies ${ }^{24-26}$ and polymerization studies ${ }^{27,28}$ of these compounds have also been performed.
Quantum chemical parameters are utilized to define the quantitative correlation between the physicochemical properties and chemical structures of organic compounds. Acidity constants can be obtained from the quantum chemically calculated Gibbs free energies of organic compounds. In literature, there have been many studies on the determination of acidity constants of organic compounds by semi-empirical and ab-initio methods in the gas and aqueous phase ${ }^{29-35}$. On the other hand, theoretical studies performed for 2aminobenzothiazoles were related to tautomerism ${ }^{36}$ and adsorption ${ }^{37-40}$.
In this study, the acidity constant values were calculated theoretically in the gas and aqueous phase
employing the ab-initio Hartree-Fock (HF) and density functional theory (DFT/B3LYP) methods for 4- and/or 6-substituted-2-aminobenzothiazole derivatives and their model compounds. Model forms of the studied molecules were created by replacing the mobile hydrogen atom with a methyl group, in order to eliminate proton migration.

## Computational Methods

Nowadays, both microscopic and macroscopic theoretical methods are available for the estimation of solvation free energies. Therefore, in principle it is possible to determine relative or absolute acidity constants, $p \mathrm{~K}_{\mathrm{a}}$ values, theoretically. Thermodynamic cycle given in Figure 1, explains the relation between the thermodynamic parameters of gas and solution phases.

The acidity constant, $p \mathrm{~K}_{\mathrm{a}}$, can be calculated by using Equations 1-2. Equation 2 is rearranged form of Equation 1.
$\Delta G=-\mathrm{R} T \ln \mathrm{~K}_{\mathrm{a}}$
$p \mathrm{~K}_{\mathrm{a}}=\Delta G_{(\mathrm{aq})} / 2.303 \mathrm{R} T$
$\Delta G_{(\mathrm{aq})}$ value in Equation 2 is determined from Equation 3 and $\Delta G_{(\mathrm{g})}^{\circ}$ value in Equation 3 is determined from Equation 4:

Figure 1 - Thermodynamic cycle illustrating the calculation of theoretical $p \mathrm{~K}_{\mathrm{a}}$ values

$$
\begin{align*}
\Delta G_{(\mathrm{aq)})}^{\circ}= & \left(\Delta G^{\circ}{ }_{(\mathrm{g})}+\Delta G_{(\mathrm{sol)}( }^{\circ}\left(\mathrm{BH}^{+}\right)-\Delta G_{(\mathrm{sol)}}^{\circ}(\mathrm{B})\right. \\
& \left.-\Delta G_{(\text {(sol) }}^{\circ}\left(\mathrm{H}^{+}\right)\right)  \tag{3}\\
\Delta G_{(\mathrm{g})}^{\circ}= & \Delta G_{(\mathrm{g})}^{\circ}\left(\mathrm{BH}^{+}\right)-\Delta G_{(\mathrm{g})}^{\circ}\left(\mathrm{H}^{+}\right)-\Delta G_{(\mathrm{g})}^{\circ}(\mathrm{B}) \tag{4}
\end{align*}
$$

Most of the values in these equations will be derived from our computations. The free energy of a proton in the gas phase $\Delta G^{\circ}{ }_{(\mathrm{g})}\left(\mathrm{H}^{+}\right)$is- $4.40 \mathrm{kcal} \mathrm{mol}^{-1}$ and its solvation free energy $\Delta G^{\circ}$ (sol) $\left(\mathrm{H}^{+}\right)$is $-260 \mathrm{kcal} \mathrm{mol}^{-1}$. These values have been used for all the $p \mathrm{~K}_{\mathrm{a}}$ calculations ${ }^{41}$.

In the present work, DFT (B3LYP/6-31G(d)) and (HF/6-31G(d)) geometry optimizations and frequency calculations were performed via the Gaussian 03W program ${ }^{42}$. All the structures were fully optimized and characterized as true minima by the absence of imaginary frequencies. The calculation of the solvation free energies was carried out by using the B3LYP/6-31G(d) method in the aqueous phase with HF (Hartree Fock) atomic radii with PCM (Polarizable Continuum Model) ${ }^{43,44}$. The total energies are given in Hartree unit, using the conversion factor of 1 Hartree $=627.5095 \mathrm{kcal} \mathrm{mol}^{-1}$. The thermodynamic parameters of 4 - and/or 6 -substituted 2 -aminobenzothiazole derivatives were calculated by employing the ab-initio HF/6-31G(d) and DFT B3LYP/6-31G(d) methods.

The Hammett equation is widely used to find out the effect of a substituent on a process in equilibrium ${ }^{45}$. When a heteroatom of a heteroaromatic compound acts as reaction site in the case of the protonation process (Figure 2 and Equation 5), "n" can be a positive, negative, or zero value:

$$
\begin{equation*}
\mathrm{BH}^{\mathrm{n}+} \rightleftharpoons \mathrm{B}^{(\mathrm{n}-1)+}+\mathrm{H}^{+} \tag{5}
\end{equation*}
$$

The Hammett equation can be written as follows in Equation 6 and 7:
$\log \mathrm{K} / \log \mathrm{K}_{\circ}=\rho \sigma$
$\log K=\rho \sigma+\log K 。$
where the K and K 。values are acid dissociation equilibrium constants of substituted and unsubstituted molecules, respectively. The $\rho$ parameter is the reaction constant. It is a measure of the sensitivity of the reaction or equilibrium to the electronic substituent effect. The parameter $\sigma$ is referred to the substituent constant and it consists of inductive and mesomeric effects, and they are mathematically addable (i.e. $\sigma_{\mathrm{T}}=\sigma_{\text {mesomeric }}+\sigma_{\text {inductive }}$ ).

## Result and Discussion

The HF and DFT/B3LYP calculated gas and solvation free energy ( $\Delta G_{\mathrm{g}}$ and $\Delta G_{\text {sol }}$ ) values for neutral molecules and their protonated cations, are given in Tables I and II. By utilizing the thermodynamic parameters, protonation acidity constants were calculated and results given in Figure 2 and Tables I and II.

An attempt was made to evaluate the results as follows:

## Basicity

The change in solvation free energy values of the investigated compounds for both $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d})$ and B3LYP/6-31G(d) calculation methods revealed that increase of total free energies indicates amino groups protonation for benzothiazole derivatives (Tables I and II, Figure 2a). The same trend was observed in nucleophilicity increase of the compounds. The compound 19 was found to be the most powerful nucleophile among the studied benzothiazole compounds in aqueous phase for both $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d})$ and B3LYP/6-31G(d) calculation methods (Table III).

According to Table I, the aqueous phase acidity constants $\left(p \mathrm{~K}_{\mathrm{a}}\right)$ values of studied molecules indicated that molecule $\mathbf{1 6}$ has the most basicity for $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d})$ method. The presence of fluorine atom at the 6-position of molecule $\mathbf{1 6}$ causes a decrease in

Figure 2 - Protonation pattern of studied (a) 2-aminobenzothiazole, (b) 2-aminothiazole derivatives and possible protonation pattern for molecule 21 (c)
electron density of amino group due to withdrawing of electrons inductively from the ring. On the other hand, it can be seen from the Table II, B3LYP/6$31 \mathrm{G}(\mathrm{d})$ method revealed that the molecule 19 has the most basicity. Due to the presence of methyl in their amino groups, it is expected that the molecules $\mathbf{2 , 5}, \mathbf{8}$, 11, 14, 17 and 19 to be more basic than the molecules of $\mathbf{1}, 4,7,10,13$ and 16; but methyl groups prevent their protonation because of steric hindrance. If the $p \mathrm{~K}_{\mathrm{a}}$ values given in Tables I and II are considered, it can be said that, the hydrogen substituted compounds $(1,4,7,10,13$ and 16) have more basic character than the methyl substituted $(\mathbf{2}, \mathbf{5}, \mathbf{8}, \mathbf{1 1}, \mathbf{1 4}, \mathbf{1 7})$ benzothiazole derivatives, for both calculation methods. Furthermore, molecules 3, 6, 9, 12, 15 and 18 have more steric hindrance due to the presence of
two methyl groups on their amino groups. Therefore, these compounds have the lowest basicity, than the one methyl substituted and unsubstituted benzothiazoles.

As can be seen from the Table IV, the aqueous phase calculations indicated that the Mulliken charge $(q)$ of amino nitrogen atom is the lowest in molecule 18 and is the highest in molecule $\mathbf{1 6}$ for $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d})$ and B3LYP/6-31G(d) methods.

The possible protonation paths were shown in Figure 2. It can be clearly seen from the structure of studied compounds that there are two potential protonation centers in each molecule. From the calculated acidity constants of 2-aminobenzothiazoles, it was detected that the protonation occurs at the nitrogen atom of the amino group rather than ring

nitrogen atom (Table I and II). The theoretical acidity constants values obtained by protonation of the amino nitrogen are consistent with the experimental acidity constant values (Figure 3).

The protonation of the studied thiazole molecules (except molecule 21) occurs at the nitrogen atom of the ring (Figure 2b). Methyl group of molecule 27 and two methyl groups on the nitrogen atom of amino group in molecule 28 prevent easy protonation of the nitrogen atoms from 3-position because of steric hindrance. Therefore, they are less basic than the molecule 26, which has no substituent on the nitrogen atom of amino group. The $\alpha$-naphthyl and $\beta$-naphthyl groups are substituted in molecules 20 and 23, respectively. While the molecule 20 is protonated from the thiazole ring, molecule 21 is protonated from amino/imino group (Figure 2c).

The molecule $\mathbf{2 3}$ is naphthyl group substituted at $\beta$ position and the molecule 20 includes the naphthyl group its $\alpha$-position. Calculated $p \mathrm{~K}_{\mathrm{a}}$ of the compound 23 shows the compound 23 does not have full conjugation compared to the molecule 20. Thus, the electron density of the nitrogen atom on the thiazole ring for $\beta$-naphthyl substituted compound increases. This leads to an increase in basicity of the molecule 23. Two methyl group substituted molecules (22 and 25) prevent protonation of thiazole ring nitrogen, due to the steric hindrance.

Experimental $p \mathrm{~K}_{\mathrm{a}}$ values of the studied molecules were plotted versus theoretically calculated $p \mathrm{~K}_{\mathrm{a}}$ values and these graphs were given in Figures 3. Acceptable correlations were observed between theoretically (HF and B3LYP) and experimental $p \mathrm{~K}_{\mathrm{a}}$ values of the molecules with regression coefficients

Figure 3 - Plot of first acidity constant values ( $p \mathrm{~K}_{\mathrm{al} \text { (calc.) }}$ ) calculated by ( $\circ$ ) HF and ( $\square$ )DFT/B3LYP methods in aqueous phase versus the experimental acidity constants $\left(p \mathrm{~K}_{\mathrm{a}(\text { expt.) }}\right)$ for studied (a) 2-aminobenzothiazole, (b) 2-aminothiazole derivatives

Figure 4 - The plot of ( $\circ$ )HF and ( $\square$ )DFT/B3LYP aqueous phase calculated substituent constant $\sigma_{\text {(calc.) }}$ values, and experimental substituent constant, $\sigma_{\text {(expt.) }}$, for studied (a) 2-aminobenzothiazole, (b) 2-aminothiazole derivatives
$\left(R^{2}=0.98,0.86\right)$ and $\left(R^{2}=0.98,0.85\right)$ for the protonation of benzothiazole and thiazole molecules, respectively. Calculated $p \mathrm{~K}_{\mathrm{a}}$ values in Table I and II supports that protonation of aminothiazoles occurs at the ring nitrogen atoms (Figure 3). As it can be seen from the obtained regression coefficients, the HF method gave better results as compared to the DFT method.

It is now possible to discuss that the position and the size of substituent effects on the basicities of studied molecules can be evaluated from the calculated $\sigma$ values (Table V).

## Substituent effects

The application of the Hammett equation to heterocyclic systems was described in section 2 . The Hammett equation can be used to elucidate the reaction pathways and to ascertain the effect of substituent. In the present work, the substituent constant ( $\sigma$ ) values for some benzothiazoles and thiazoles can be calculated by using Equation 7.

When the experimental $\sigma$ values are taken into consideration, it is observed that molecules $\mathbf{4}, \mathbf{5}, \mathbf{1 6}$, 19 have negative charges and the methyl groups on

4 -and/or 6-positions have electron donating effect. It was also observed that, connection of the $\alpha$-naphthyl and $\beta$-naphthyl groups to the thiazole ring cause electron withdrawing effect due to the $\sigma$ values of molecules 20, 22, 23 and 25 being positive. It was seen that the ab-initio and DFT methods give concordant results with the experimentally determined $\sigma$ values (except for molecule 5 calculated by HF method).

A graph of the experimental $\sigma$ values plotted against the calculated $\sigma$ values can be seen in Figure 4. Acceptable correlations were observed between theoretical (HF and DFT/B3LYP) and experimental substituent constants, with the regression coefficients of $\mathrm{R}^{2}=0.99,0.99,0.74,0.94$ for benzothiazole and thiazole derivatives, respectively.

## Acknowledgement

This study is dedicated to the memory of our colleague Prof. Cemil Öğretir, who died on January 19, 2011. The authors would like to thank the Eskişehir Osmangazi University for providing the Gaussian 03W program.
